

February 2025 Crypto Market Overview and Daily Trading Strategy

Market Overview

The cryptocurrency market is coming off a volatile January and a turbulent start to February. Bitcoin reached a new all-time high of around \$109,000 on January 20th amid bullish post-halving momentum

financemagnates.com

, but sentiment sharply reversed as macroeconomic shocks hit in early February. Over the weekend, U.S. President Donald Trump announced **25% tariffs on imports from Canada and Mexico**, sparking fears of a trade war and a broad risk-off move across markets

financemagnates.com

. Global stocks sold off (Dow futures -1.4%, S&P 500 -1.9%) and the U.S. dollar surged ~1% on the news

financemagnates.com

, creating a **strong headwind for crypto**. As a result, **Bitcoin plunged about 14%** to a three-week low near \$91,000, and altcoins saw an even deeper “**bloodbath**” – Ethereum dropped ~20%, while XRP crashed ~30% to multi-week lows

financemagnates.com

financemagnates.com

. The **total crypto market cap** shed nearly 10%, threatening to fall below \$3 trillion if the rout continued

cryptodaily.co.uk

. This panic-driven selloff reflected **extremely negative sentiment**, with investors rushing for safety.

Despite the fearful atmosphere, high-risk traders see opportunities in the volatility. **Market sentiment indicators** swung toward extreme fear after the crash, but contrarian analysis suggests a potential short-term bottom. On February 3, Bitcoin tested the **critical support around \$92,000**, a level that had held firm for over two months

financemagnates.com

. Indeed, **technical analysis showed strong support at \$92K** and hinted at recovery signals as buyers stepped in at the lows

financemagnates.com

. Massive **liquidations** of leveraged positions also occurred – over **\$2.2 billion in crypto futures positions were wiped out** as prices plunged

coindesk.com

. Such a liquidation flush often marks capitulation, removing weak long positions and potentially “**ending the price correction**,” thereby providing a base for a relief rally

coindesk.com

coindesk.com

. Analysts note that **high liquidation volumes can indicate an overstretched sell-off** and create a support zone where selling pressure eases

coindesk.com

. In other words, the worst of the drawdown may be over, setting the stage for a “buy the dip” scenario if fundamentals remain intact.

Looking ahead, **market trends** will likely be dominated by the interplay of technical rebounds and macro news. Key **macroeconomic factors** to watch in February include further trade war developments, monetary policy signals, and inflation data. Notably, Trump has hinted at extending tariffs to the European Union “pretty soon,” which could spook markets again

coindesk.com

. However, there are also signs of de-escalation – for example, the U.S. and Mexico agreed on Feb 3 to **pause the new tariffs for one month**, easing immediate fears

m.economictimes.com

m.economictimes.com

. This gave a positive jolt to market sentiment and contributed to Bitcoin trimming its losses (back above \$95K) by Monday’s close. Additionally, investors will be closely watching the **U.S. inflation report due on Feb 12, 2025**

bls.gov

. Persistently high inflation could keep the Federal Reserve hawkish and pressure crypto, whereas a cooler-than-expected CPI print might improve risk appetite. The recent jump in short-term Treasury yields (and drop in 10-year yields) reflects **concerns about near-term inflation** and growth, which have been weighing on crypto prices as well

coindesk.com

. In short, February is expected to be a **roller-coaster** month where news-driven swings are amplified.

In this context, achieving a **1% daily gain** will require nimble, high-risk trading – **capturing short-term trends, reversals, and breakouts**. Traders will lean on technical indicators (like RSI, MACD, and moving averages) to time entries and exits, while keeping an ear to the ground for news that could sway market sentiment overnight. **Volume and liquidity analysis** will be crucial too: rising volumes on up-days may confirm bullish moves, whereas thinning liquidity in a sell-off could signal a climax of panic or an oncoming reversal. Given the heightened volatility, **all trade recommendations will use fixed position sizes** (a consistent amount per trade) rather than percentage-based allocations – this ensures the strategy is clearly defined (e.g. buy or sell a fixed number of units each day) and avoids compounding risk on a larger portfolio. What follows is a deep dive into **BTC, ETH, XRP, and SOL** with analysis of their individual

outlooks, and a **day-by-day trading plan for February** that leverages the insights from trends, technicals, volume, and news.

Bitcoin (BTC)

Trend & Sentiment: Bitcoin (BTC) enters February on a shaky footing after a steep drop. It **fell from ~\$102K to the \$91K–\$95K range in early February** amid the broader market sell-off

financemagnates.com

financemagnates.com

. This erased late-January gains and put the short-term trend in bearish territory. Market sentiment turned fearful – evidenced by four consecutive days of decline and traders abandoning risk assets during the tariff scare

financemagnates.com

cryptodaily.co.uk

. However, BTC's **long-term uptrend** (established in late 2024's bull run) may still be intact. The **key level to watch is ~\$92,000**, which marks the lower boundary of Bitcoin's recent consolidation range

financemagnates.com

. Bulls have vigorously defended this support in the past (it was tested about 8 times in recent months), and once again buyers stepped in around \$91–92K during the Feb 3 dip. **If this floor holds, sentiment could quickly stabilize**. Notably, by Feb 3 evening BTC recovered to ~\$95K

financemagnates.com

after dipping to \$91K, suggesting buy-the-dip appetite. As one analyst noted, previous **Trump-era tariff shocks tended to be short-lived**, with the general bullish trend resuming after the initial panic

coindesk.com

. This history gives bulls hope that BTC can regain an upward trajectory once the trade war news is digested.

Technical Indicators: Bitcoin's technical picture reflects the recent weakness but also hints at a possible bottom. On the **daily chart**, BTC **plunged below its 20-day simple moving average (SMA)** late January and **fell through the 50-day SMA** during the first February weekend

cryptodaily.co.uk

, a clearly bearish development. The **Relative Strength Index (RSI)** has dropped to 38 – well below the neutral 50 level – indicating BTC is nearing **oversold conditions** after the sell-off

cryptodaily.co.uk

. In tandem, the **MACD** on daily timeframe has turned decisively negative, confirming **downward momentum**

cryptodaily.co.uk

. These bearish signals warrant caution; however, an oversold RSI can also presage a relief rally, especially when coupled with a strong support zone (like 92K). On shorter timeframes (4H or 1H charts), traders likely observed bullish divergences or bottoming patterns around Feb 3 as BTC bounced off support. **Moving averages:** BTC is still above its 200-day EMA around ~\$83K (which is an important long-term support)

financemagnates.com

. Analysts note that only a break **below the 200-day EMA (~\$83K)** would truly threaten the broader uptrend

financemagnates.com

. On the upside, **\$100K is the psychological resistance** now – Bitcoin needs to reclaim six figures to flip the daily sentiment back to bullish

cryptodaily.co.uk

. Above \$100K, the next resistance is in the \$106K–\$109K zone (recent high). In summary, BTC's technicals show short-term bearishness (low RSI, MACD down) within a larger bullish context, meaning there's room for a **technical rebound** if buyers can push the price back above key averages.

Volume & Liquidity: The panic sell-off was accompanied by a **surge in volume**. Exchange volumes spiked as investors rushed to exit, and the **futures market saw over \$400M BTC longs liquidated** in 24 hours

financemagnates.com

. Importantly, **Ethereum actually had even higher liquidations (\$612M)**, indicating **cross-market deleveraging**

financemagnates.com

. This capitulation-style volume can be interpreted positively: it flushed out leverage and could leave **fewer sellers in the near term**, since many weak hands have already sold. Order book data (per CoinDesk) shows that the ~\$92K area coincided with large buy orders, reinforcing it as a liquidity pocket where BTC finds support

financemagnates.com

. **Liquidity** in BTC remains high (it's the largest crypto with deep order books), but during extreme moves even BTC can experience slippage – evidenced by the rapid drop to \$91K. Going forward, watch for **volume confirmations**: rising volume on up-days will validate any rally (signaling genuine demand returning), whereas declining volume on a bounce could warn that the move lacks conviction. Additionally, the **BTC dominance** metric ticked up during the crash as altcoins fell harder, implying some rotation into the relative safety of Bitcoin. If dominance continues to rise, BTC may lead the market recovery, whereas a sharp drop in dominance could mean capital rotating to alts once stability returns.

News & Macro Factors: Bitcoin, as the bellwether of crypto, will react to all major news mentioned in the overview. **Trade war developments** are front and center – any indication of further escalation (e.g. an abrupt announcement of EU tariffs) could pressure BTC price again. Conversely, diplomatic resolutions or delays (like the tariff pause with Mexico) tend to spark relief rallies

m.economictimes.com

m.economictimes.com

. **Macroeconomic data** such as U.S. inflation on Feb 12 is another big factor. If inflation runs hot, expectations of prolonged high interest rates (already a concern weighing on markets cryptodaily.co.uk) could harm BTC as investors fear less liquidity and more Dollar strength. Indeed, Bitcoin's drop has been partly attributed to a “**strong dollar, weak Wall Street**” environment

financemagnates.com

. On the other hand, any surprise dovish signals or cooling inflation could trigger a risk-on response benefiting BTC. Additionally, **regulatory news** remains in focus. There are positive undercurrents: for instance, reports indicate the **SEC has cleared a Bitwise Bitcoin-Ethereum ETF for launch**, pending final trading approval

financemagnates.com

. Such developments, if finalized in February, could significantly boost market sentiment by attracting institutional capital. Overall, BTC's outlook for February is a tug-of-war between **macro-driven fear and crypto-specific optimism**. High-risk traders will need to stay agile – ready to short BTC on negative news spikes, but also ready to “**buy the dip**” when technicals show oversold conditions or when supportive news (like easing trade tensions or regulatory green lights) emerge.

Ethereum (ETH)

Trend & Sentiment: Ethereum (ETH) has mirrored Bitcoin's trajectory, but with amplified moves. Prior to the drop, ETH was in a strong uptrend, even attempting a breakout above ~\$3,400 in late January

verifiedinvesting.com

. However, the early-February crash hit ETH especially hard. In the 24 hours of carnage, **ETH fell over 20%**, a sharper decline than BTC

financemagnates.com

. This brought ETH from about \$3,300 at Jan's end down to roughly **\$2,150 at the nadir** on Feb 3

cryptodaily.co.uk

financemagnates.com

, which actually tested its August lows. The sentiment among ETH traders turned extremely bearish during this plunge – evidenced by the fact that **ETH saw the highest liquidations of any asset (\$611M) during the drop**

financemagnates.com

, indicating many leveraged longs got wiped out. Despite the fear, ETH did stage a significant rebound off the lows: by Feb 3 it recovered to **~\$2,600** (about +20% from the bottom)

cryptodaily.co.uk

. This rebound suggests that **\$2,150 is a strong support** (it aligned with a major horizontal level and Fibonacci 78.6% retracement around \$2,000)

cryptodaily.co.uk

. Market sentiment for ETH is now cautiously optimistic that the worst is over, at least in the short term. The question is whether ETH can quickly regain its previous range above \$3,000, or if it will lag behind BTC in recovery. One point of hesitation: some analysts argue that **ETH's upside might be limited in the immediate term** compared to other beaten-down alts, since it still has a large market cap and bounced already

cryptodaily.co.uk

. Nonetheless, if broader crypto sentiment improves, ETH is likely to follow BTC's lead out of the downturn, albeit with continued higher volatility.

Technical Indicators: Technically, Ethereum underwent a **drastic correction** but is trying to stabilize. It decisively **broke below its 50-day SMA** during the crash and is currently hovering below the **\$3,000 mark**, which had acted as support previously

cryptodaily.co.uk

. The daily **RSI for ETH plunged well into oversold territory** during the drop (likely falling into the 20s). This oversold condition implies ETH was *very stretched to the downside*. As of early February, the RSI has curled upward off the lows but remains below neutral, reflecting a tentative recovery. The daily **MACD** on ETH turned bearish as well – a bearish crossover occurred amid the sell-off and the MACD histogram is still negative, signaling that downward momentum has not fully dissipated. However, the extreme magnitude of the drop means we could be seeing a “*false breakdown*” – indeed one analysis noted ETH made a false breakout below two support levels and that **sideways trading around current prices (~\$2.6K) is likely for a few days** as it digests the move

u.today

. In other words, ETH may consolidate in a range (perhaps \$2,400–\$2,800) in the short term, allowing its indicators to reset. **Key levels:** On the downside, \$2,150 (the recent low) and \$2,000 are critical support levels – if these fail, ETH could see \$1,800 or lower. On the upside, ETH faces resistance at **\$3,000** (a round number and prior support), followed by about **\$3,275–\$3,300** (the region of the 50-day EMA and the last swing high)

verifiedinvesting.com

. A move above ~\$3,300 would indicate the bullish trend is back on track. **Moving averages:** The 20-day EMA for ETH has started sloping down due to the drop, and ETH will need to climb above it (currently in the \$2.9K area) to regain short-term bullish momentum. Given the recent bounce, shorter-term indicators like the stochastic RSI on 4H charts have likely turned up from oversold, which could support a continued rebound. In summary, ETH's technical posture is damaged but repairable – it's in a **reset phase**, where establishing a higher low and reclaiming lost support levels (now resistances) will be the objectives for bulls.

Volume & Liquidity: Ethereum's trading volumes exploded during the sell-off. As mentioned, ETH led in liquidations, meaning many positions got force-sold, contributing to the high volume. **Spot and derivatives volumes** for ETH were significantly above average on Feb 2–3, which is typical in a capitulation event. The fact that ETH's drop was more severe suggests that **liquidity**

in ETH might have been thinner or more fragile than BTC's at that moment – large sell orders pushed ETH price down fast until major buy support kicked in around \$2,150. Now that those leveraged positions have been cleared, ETH's order books may be more balanced.

Liquidity-wise, ETH is the second-largest crypto, so it generally has deep markets; however, compared to BTC, it can exhibit larger percentage swings as seen. Going forward, a key indicator will be **ETH/BTC relative strength** – after the crash, ETH/BTC likely weakened (meaning ETH fell more against Bitcoin). If confidence returns, we might see ETH/BTC rise, indicating traders rotating back into ETH for higher beta gains. Another volume indicator: watch **DeFi activity and stablecoin flows on Ethereum's network**. In uncertain times, users might park funds in stablecoins (we did see increased demand for stablecoins during the turmoil

coindesk.com

coindesk.com

). If that capital starts flowing back into ETH or ETH-based assets, it could signal renewed buying interest. In practical trading terms, expect **elevated intraday volatility** for ETH – its liquidity is ample for large trades, but price can move \$100+ in minutes when momentum picks up, which is both an opportunity and a risk for day traders.

News & Macro Factors: Ethereum's fundamental narrative in February is influenced by both macro and crypto-specific news. On the macro side, ETH will react similarly to BTC on things like tariff news, stock market moves, and interest rate outlook. Being a higher beta asset, ETH may swing harder on the same news (e.g., a positive development could see ETH outpace BTC's gains percentage-wise, and vice versa for negative news). One particular item to watch is any news on **Ethereum network upgrades or scaling developments** – although none are specifically slated for February, unexpected announcements (for instance, progress on Ethereum's Proto-Danksharding or layer-2 adoption milestones) could boost sentiment. Additionally, **regulatory clarity or institutional adoption news** can be a catalyst: the mention that an ETF including Ethereum has been cleared

financemagnates.com

is a medium-term bullish factor. If that ETF gets final approval to begin trading, it might spark direct buying of ETH for fund purposes. Another factor is **competition from other layer-1 chains** (like Solana) – however, given the across-the-board drop, February's story is less about one platform vs another and more about macro sentiment. Finally, Ethereum's role in DeFi means **liquidity mining and yield trends** could indirectly affect ETH demand. If crypto yields spike (sometimes happens when prices drop and protocols increase incentives), it could attract capital back into ETH to deploy in DeFi. In summary, Ethereum will largely take cues from the overall crypto market's risk appetite in February. Traders aiming for daily gains will treat ETH as a slightly more volatile extension of the BTC trend, adjusting position sizes accordingly and watching for **any divergence** (if ETH starts moving independently due to some news, that could present trading setups on the ETH/BTC pair as well).

Ripple (XRP)

Trend & Sentiment: Ripple's XRP token experienced an exceptionally wild ride. XRP was already struggling to build on its January highs (it traded above \$3.00 for much of late January) when the market turned south. The sell-off drove XRP **below its ascending trendline** and through multiple support levels in a matter of days

cryptodaily.co.uk

. From about \$3.12 on Feb 1, XRP crashed to an intraday low of **\$1.77** on Feb 3 before bouncing back above \$2.00

cryptodaily.co.uk

. That intraday swing was enormous, highlighting XRP's high volatility. Overall, XRP fell roughly **30%+ to a low not seen since December**

financemagnates.com

. Sentiment for XRP went from cautiously bullish (early in the week) to outright panic by the weekend. By Feb 2, **bearish sentiment intensified** as XRP slipped below its 50-day SMA and key psychological levels

cryptodaily.co.uk

. The token did manage to recover to ~\$2.38 by Feb 3

cryptodaily.co.uk

, suggesting that sub-\$2 prices were quickly bought up – likely because many see value in XRP at those depressed prices, especially given its prior uptrend. It's worth noting that **XRP had strong fundamental news in late 2024** (resolution of its SEC lawsuit, increasing adoption for cross-border payment use cases, etc.), which propelled it above \$3. This context means some bulls remain confident despite the setback, viewing the drop as a high-risk entry opportunity. However, in the immediate term, XRP must overcome very negative near-term momentum. Traders are split: some are trying to “knife catch” the bottom for a quick rebound trade, while others remain cautious until XRP confirms a trend reversal (e.g., by reclaiming lost support). The **sentiment can be described as tentative** – there's relief that XRP didn't sustain below \$2, but there isn't full confidence yet for a rally.

Technical Indicators: XRP's technical picture was severely damaged by the rapid drawdown. On the **daily chart**, XRP **sliced through its 20-day and 50-day moving averages** during the fall

cryptodaily.co.uk

, and those MAs may now act as overhead resistance (the 50-day SMA lies around ~\$2.50).

The **RSI for XRP is well below the neutral zone**, pointing downward – a clear sign of **bearish momentum** and oversold conditions

cryptodaily.co.uk

. In fact, the RSI got so low that XRP is arguably deeply oversold, which often precedes a corrective bounce. Similarly, the **daily MACD is bearish** (the MACD line crossed below the signal line, and the histogram is red)

cryptodaily.co.uk

, indicating that the downtrend could continue unless strong buying intervenes. A positive sign is that Monday's recovery brought XRP back above the \$2.00 mark and towards \$2.40, which is an attempt to **climb back within its previous range**. **Key levels** to watch: Support now stands

at **\$2.00** (a round number and recent bounce level). Below that, **\$1.50** is highlighted as a possible bottom target if selling resumes

cryptodaily.co.uk

– this was mentioned as a worst-case downside if XRP can't hold \$2. On the upside, **\$2.50 is the immediate resistance**, as it roughly coincides with the 50-day SMA and was an area where buyers previously struggled

cryptodaily.co.uk

cryptodaily.co.uk

. Beyond \$2.50, the next target would be ~\$3.00 (the level it held before the crash). To truly flip bullish again, XRP would need to **establish a higher low and break above \$3.12** (the recent swing high on Jan 30). For now, technical indicators favor a cautious approach – perhaps a consolidation between \$2 and \$2.5 as XRP rebuilds strength. Traders will likely use intraday indicators (like 1-hour RSI/MACD) to catch shorter swings; for instance, at the \$1.77 low, very short-term RSI was extremely oversold, which corresponded with the sharp bounce. Going forward, look for **bullish divergences** (e.g., price makes a lower low but RSI makes a higher low) as potential early signs the downtrend is ending.

Volume & Liquidity: During the plunge, **XRP's volume skyrocketed**. XRP is known for its large and passionate trading community, and during crashes it often sees heavy turnover. The move below \$2 likely triggered stop-losses and liquidations (on XRP futures markets), adding to a cascade of volume. Once XRP hit the \$1.77 low, a wave of buying volume came in to push it back up to \$2+ – this indicates there was significant liquidity waiting on the sidelines to accumulate at bargain prices. In terms of liquidity, XRP usually has good exchange liquidity, but its order books can be thinner relative to its market cap because many XRP holders keep funds off exchanges (with a significant portion held by Ripple Labs as well). That can sometimes exacerbate moves. The huge 30% intra-day range on Feb 3 is evidence that liquidity temporarily dried up during peak fear, then flooded back. Another point: **XRP often trades somewhat independently** of BTC during normal times (due to Ripple-related news or its use-case narratives), but in this broad market sell-off it was highly correlated, just more volatile. For volume analysis, keep an eye on whether the big volume on the sell-off is followed by similarly strong volume on the rebound. Early signs show buyers are active (the rebound had robust volume), which is encouraging. If XRP enters a consolidation, volume will likely taper off; a spike in volume during consolidation could signal the next directional move (either breakout or another breakdown). In a high-risk daily trading context, XRP's liquidity is sufficient to get in and out with moderate position sizes, but slippage can be an issue on dramatic moves, so traders might use limit orders around key levels to avoid chasing price too much in fast markets.

News & Macro Factors: XRP's price action in February will be influenced by a mix of broader market sentiment and Ripple-specific developments. On the broad side, any improvements or deteriorations in the crypto market sentiment (driven by macro news like tariffs or by Bitcoin's trend) will affect XRP. If Bitcoin and ETH start recovering steadily, that **"risk-on" wave** could benefit XRP disproportionately (since it fell more, it might rebound more in percentage terms). Conversely, if macro jitters persist, XRP could be harder hit due to its historical volatility. It's also worth considering **news specific to XRP/Ripple**: for instance, any updates on Ripple's legal

front or partnerships. By 2025, Ripple's lawsuit with the SEC over XRP's status largely concluded in Ripple's favor (with XRP not deemed a security for retail sales), which was a major overhang removed. This means regulatory risk for XRP is lower than it was in previous years, a positive fundamental that could attract buyers on dips. If February sees any announcements of new Ripple partnerships (especially with banks or payment providers) or progress in CBDC projects involving XRP Ledger, those could spur bullish sentiment for XRP. Additionally, **Ripple's scheduled token releases or sales** (escrow unlocks) can sometimes add minor selling pressure; traders might watch if any large XRP releases are due in February, though Ripple has been disciplined in managing sales. On the adoption front, if broader crypto usage picks up (for example, remittance flows or on-demand liquidity using XRP increase due to some event), that could be a tailwind. However, these are secondary to the macro theme this month. In essence, **XRP will mainly trade on technical and sentiment grounds in February**, as the community looks for a trend reversal. High-risk traders will capitalize on XRP's swings by staying alert to both the **market-wide cues** (like another leg of volatility from macro news) and any **whispers in the XRP community** that could signal incoming large moves (for example, sometimes coordination on social media or whale movements can lead to sudden spikes).

Solana (SOL)

Trend & Sentiment: Solana (SOL), a high-profile altcoin, was not spared from the crypto rout, though its decline was somewhat less in percentage than some smaller alts. Over the same tumultuous weekend, **SOL fell about 24%** from its highs, dropping from roughly the mid-\$200s down to around **\$185** at the worst point

cryptodaily.co.uk

. This move took SOL **below a major support at \$185** and even briefly undercut the 61.8% Fibonacci retracement of its prior rally

cryptodaily.co.uk

. Sentiment for Solana turned bearish as well, especially since \$200 was a key psychological support that the market hoped would hold. By Monday (Feb 3), Solana's attempted rebound only managed to **confirm \$202 as a new resistance level** – meaning, when SOL tried to climb back, it struggled to move above \$200-\$202, which had been support before

cryptodaily.co.uk

. This has put traders on alert that Solana might be in for more downside unless it can quickly regain that level. On the other hand, there is a silver lining: **shorter-term momentum oscillators for SOL (like stochastic RSI up to the daily) all hit bottom and started turning up**, suggesting the **sell-off momentum is waning and a bounce is underway**

cryptodaily.co.uk

. Indeed, SOL has already bounced off its lows (from ~\$170 back to the ~\$190 range by Feb 3-4). The broader sentiment on Solana is mixed – fundamentally, Solana had positive buzz coming into 2025 (with growing ecosystem projects, NFT activity, etc.), but it's also known for being more volatile and occasionally suffering technical network issues. The high-risk trading crowd views SOL as an attractive asset for quick gains due to its volatility, but they are also wary of its sharp drops. **In February, sentiment on SOL will likely follow the general altcoin**

recovery narrative if one materializes, with traders watching if SOL can reclaim \$200 (which would restore some confidence).

Technical Indicators: Solana's technical setup took a hit but shows potential for stabilization. **RSI (14)** on the daily for SOL fell below neutral (50) and pointed downward during the crash, reflecting rising bearish momentum

cryptodaily.co.uk

. It likely approached the oversold threshold (~30) at the lows, indicating SOL was close to being oversold. The **MACD** for SOL has turned bearish as well (the MACD line crossed below zero), reinforcing the short-term downtrend signal

cryptodaily.co.uk

. However, with the recent small rebound, we might see the RSI flatten out and possibly form a bullish divergence if SOL doesn't make new lows. **Support levels:** As mentioned, around **\$170-\$185** is a support zone (it includes the \$185 horizontal support and \$170 as the next support, with \$150 being the 78.6% Fibonacci level below that)

cryptodaily.co.uk

cryptodaily.co.uk

. These levels are reference points for any further sell-off – if SOL were to slip again, \$170 and then \$150 are possible downside targets where buyers could step in. On the upside, **\$200-\$202** is immediate resistance (prior support now flipped)

cryptodaily.co.uk

. SOL needs to close above \$202 to negate the recent breakdown. Above that, the **50-day moving average** (which is probably around the low \$220s now) would be the next resistance to watch. A notable technical feature for Solana is its historical tendency to have V-shaped recoveries after large drops, often driven by eager buyers in its community; traders might anticipate something similar if the overall market allows. In terms of **trend structure**, SOL's drop may have broken its short-term uptrend line, meaning it could oscillate in a range for a while. Short-term traders will monitor intraday charts for breakouts: for example, if SOL can break above \$202 with volume, it could quickly run toward \$220; if it falls below \$180 again, a retest of \$170 or \$160 could happen. For now, **indicators like Stochastic RSI and shorter EMAs** suggest the worst of the momentum is behind, but confirmation (in the form of regained levels) is needed before declaring an uptrend resumption. High-risk strategy for SOL will involve playing these support-resistance flips – essentially trading the volatility between \$170 and \$220 until a directional trend asserts itself.

Volume & Liquidity: Solana's volume spiked during the sell-off, though in absolute terms it's lower than BTC or ETH. SOL trading tends to concentrate on major exchanges and also on decentralized exchanges within Solana's ecosystem. The plunge to sub-\$185 likely triggered a lot of stop orders and possibly liquidations in SOL futures (for instance, on exchanges like Binance or FTX). Liquidity for SOL is generally good, but it can thin out during panic – that's why we saw a quick drop through support. Once SOL neared \$160-\$170, bargain hunters likely rushed in, providing a liquidity backstop. It's worth noting that earlier in January, SOL had strong volumes on its up days, reflecting genuine interest; those participants might return now that

price is much lower. Another liquidity aspect: **Solana's on-chain activity** – if network usage (transactions per second, active addresses) remains robust through the market dip, it shows fundamental interest which can help price recovery. As of now, there's no sign of a mass exodus from Solana ecosystem, so the sell-off was more about market-wide deleveraging than Solana-specific issues. For daily trading, SOL offers decent liquidity to enter/exit positions, but it can move a few percentage points in a very short time. Traders should be cautious of any **network outages or slowdowns** (Solana had some in the past) – none are reported currently, but such an event could severely impact short-term trading. In terms of volume signals, if SOL's bounce is accompanied by increasing volume, that would indicate buyers are coming in forcefully (bullish sign). If volume dies down and SOL drifts, it might be waiting for a catalyst or following the rest of the market.

News & Macro Factors: Solana-specific news in February could revolve around network developments or ecosystem growth. Any news of **network upgrades** (to improve performance or stability) would be welcomed by investors and could differentiate SOL's performance. Additionally, **ecosystem news** – such as popular new DApps launching, or major NFT sales on Solana, or venture funding going into Solana projects – can bolster confidence in SOL's long-term value, potentially attracting dip-buyers. On the macro side, SOL will largely move with the altcoin pack; it doesn't have a direct macro tie, but it is sensitive to overall risk appetite. If investors flip bullish on crypto broadly, SOL could see outsized gains (given it's down from ~\$260 highs to under \$200 now). Conversely, if fear persists, SOL's high beta nature means it could be sold off further. One specific factor: **competition and rotations within layer-1 coins**. Solana often is in a basket alongside other smart contract platform tokens (like Cardano, Polkadot, etc.). If, say, Ethereum shows strength, sometimes SOL benefits as well (general layer-1 enthusiasm), but other times capital rotates out of one into another. So watch the comparative performance – if Solana significantly lags others, it might suddenly play catch-up (a trading opportunity), or if it runs up too fast, traders might rotate profits to other coins. Additionally, **any commentary from the U.S. administration or regulators about crypto technology** could indirectly affect SOL, especially since Solana is known for speed and could come into discussions about scalable blockchain solutions. But those are peripheral possibilities. In summary, **Solana's fate in February will track the broader crypto recovery** if one materializes, with an added kicker that it could move more dramatically. High-risk traders will aim to exploit SOL's large swings by being positioned when it breaks key technical levels, all while keeping an eye on the general market tone and any Solana-specific headlines.

Daily Buy/Sell Recommendations for February 2025

Below is a **day-by-day trading plan** for BTC, ETH, XRP, and SOL, aiming for approximately **1% profit per day** through high-risk trades. Each day is marked with a **Buy** (enter a long position at or near the start of the day) or **Sell** (enter a short position or exit longs) signal for each coin, along with a brief rationale. All trades assume using a *fixed amount* of capital/coin (not a percentage of a portfolio) for clarity. This plan is based on the analysis above – it factors in technical setups, expected market reaction to news/macro events, and typical price patterns. Adjustments may be needed in real-time as volatility unfolds, but this provides a structured roadmap for February.

Date	BTC (Action & Rationale)	ETH (Action & Rationale)	XRP (Action & Rationale)	SOL (Action & Rationale)
Feb 1 (Thu)	Sell/Short – Bearish break below support as tariff fears hit; BTC lost its 20-day MA, signaling further downside cryptodaily.co.uk .	Sell – ETH tumbles below \$3K on panic; momentum turning down sharply cryptodaily.co.uk , best to short the weakness.	Sell – XRP trendline broken and below moving averages cryptodaily.co.uk ; heavy selling pressure indicates more downside.	Sell – SOL falls below \$200 support; bearish sentiment and trend breakdown suggest continuing decline cryptodaily.co.uk .
Feb 2 (Fri)	Sell – Continued risk-off trading; BTC nearing ~\$100K fails to hold and slides further amid broad market sell-off reuters.com .	Sell – ETH freefalls (~-20%) with market; stay short until a clear support (around \$2.2K) is hit financemagnates.com .	Sell – XRP plummets (down ~10%+) below \$2.50 and 50-day SMA cryptodaily.co.uk ; maintain short as bearish momentum persists.	Sell – SOL weakness ongoing; loses key Fibonacci support (\$185) cryptodaily.co.uk , so continue short to ride downward momentum.
Feb 3 (Sat)	Sell – Early in the day, sentiment is capitulatory. BTC breaks below \$100K decisively cryptodaily.co.uk . Remain short; watch \$92K support intraday.	Sell – ETH still under intense selling; targeting the major support ~\$2,150 cryptodaily.co.uk . Keep short until buyers appear at lows.	Sell – XRP in freefall in morning, slips under \$2.00 intraday cryptodaily.co.uk ; stay short, anticipating possible \$1.5–\$1.8 bottom area.	Sell – SOL slides toward next supports (\$170) as panic selling continues cryptodaily.co.uk . Short into any weak bounces, expecting a bottom soon.

Feb 4 (Sun)	<p>Buy – Market likely bottomed overnight around \$91K financemagnates.com</p> <p>. BTC bouncing off oversold RSI ~38 cryptodaily.co.uk</p> <p>and strong \$92K support financemagnates.com</p> <p>– enter long to capture the rebound.</p>	<p>Buy – ETH found support near \$2.15K cryptodaily.co.uk</p> <p>and bounced ~20% to ~\$2.6K cryptodaily.co.uk</p> <p>. Oversold conditions imply a relief rally; go long for bounce back toward \$2800+.</p>	<p>Buy – XRP rebounding after flash-crash to \$1.77 cryptodaily.co.uk</p> <p>. With price back above \$2.0, a local bottom is likely; go long aiming for a move toward \$2.5 u.today</p> <p>.</p>	<p>Buy – SOL's momentum flip: Stoch RSI bottomed cryptodaily.co.uk, and price recovering from ~\$170. Go long as Solana attempts to reclaim \$200 (new resistance) on the bounce.</p>
Feb 5 (Mon)	<p>Buy – Bullish follow-through expected. BTC closed above \$92K (bulls defended) financemagnates.com</p> <p>and is trending upward towards \$100K. Go long to ride upside, but be ready to take profit near \$100K resistance.</p>	<p>Buy – ETH likely to trade sideways/up around \$2600 u.today</p> <p>, consolidating after big rebound. Enter long on minor dips, targeting ~1–2% intraday swings as volatility remains high.</p>	<p>Buy – XRP momentum shifting up after reclaiming \$2.38 cryptodaily.co.uk</p> <p>. Long position to catch a further bounce to test \$2.5 (50-day SMA) – a key level for a bullish flip.</p>	<p>Buy – SOL continues relief rally. With all shorter-term RSIs rising, long SOL aiming to break above \$200; potential quick gain if \$202 resistance cracks cryptodaily.co.uk</p> <p>.</p>
Feb 6 (Tue)	<p>Sell – Take profits / Short at resistance. BTC approaches the critical ~\$100K level but struggles to break above on first test cryptodaily.co.uk</p> <p>. Sell into strength (or open a short) anticipating a pullback from the psychological barrier.</p>	<p>Sell – ETH nears \$2800–\$2900 (approaching 20-day MA) and may stall. Sell to secure gains; RSI off lows but not yet bullish, suggesting a pullback or consolidation.</p>	<p>Sell – XRP hits ~\$2.50 (major resistance at 50-day SMA) cryptodaily.co.uk</p> <p>. Likely profit-taking here – sell the position as upside momentum slows at this hurdle.</p>	<p>Sell – SOL runs into the \$200–\$202 ceiling cryptodaily.co.uk</p> <p>. If price cannot close above \$202, assume a short-term top – sell now, as charts show prior support turning into resistance.</p>

Feb 7 (Wed)	Sell – Minor retracement day. After failing at \$100K, BTC might dip back to mid-\$90Ks. Stay short or out as price corrects slightly; bearish MACD still in play short-term cryptotoday.co.uk .	Sell – ETH likely pulls back from ~\$2800 toward support ~\$2600. Short in the morning or hold no long positions; let it retest lower support before buying again.	Sell – XRP could retrace towards \$2.2–\$2.3 after rejection at \$2.5. Enter a short-term short to profit from this dip, watching \$2.20 support.	Sell – SOL unable to break \$200 convincingly may slip to ~\$180s again. Short to capitalize on this secondary dip, eyeing \$180 support zone.
Feb 8 (Thu)	Buy – BTC expected to find support around mid-\$90K (perhaps \$94–\$95K). If selling pressure eases by morning, go long at support for a bounce. Goal: capture a swing from mid-\$90Ks back toward \$100K.	Buy – ETH likely stabilizes around \$2600 (false breakdown passed u.today). Go long on this dip; oversold bounce potential if buyers defend \$2600 area for a second time.	Buy – XRP dips appear to hold above \$2.20 – a higher low vs earlier \$1.77 low, indicating stabilization. Go long around \$2.3, aiming for another push toward \$2.5 as sentiment improves.	Buy – SOL in dip-buy territory again (~\$180). With broader market steadier, long SOL expecting another attempt at \$200; short-term oscillators resetting give room for upside.
Feb 9 (Fri)	Buy – Market sentiment turning cautiously optimistic into the weekend. BTC may make another run at five-figure (100K) territory. Stay long from prior day or add on any intraday weakness, targeting +1% or more on a continued climb.	Buy – ETH showing resilience in high-\$2Ks. Long ETH as it could grind upward toward \$2800+ once more. The ATR has been large, so even a “sideways” day offers 1% range to capture u.today .	Buy – XRP consolidating in the low \$2s but with bullish bias after that brutal drop. Continue to buy low and sell higher intraday; today lean long, expecting XRP to creep back up near \$2.5 resistance again.	Buy – SOL sentiment improves if BTC/ETH are rising. Long SOL during the day – it could retest \$200 over the weekend. Watch volume; increasing buy volume would confirm this upside attempt.
Feb 10 (Sat)	Buy – BTC often sees weekend volatility. This Saturday, anticipate an upward bias as traders front-run next week’s potential catalysts. Long BTC aiming	Buy – ETH likely follows BTC – possibly more volatile on weekend. Go long; if BTC pushes up, ETH could jump a few percent toward the \$3000 mark quickly.	Buy – XRP enters the weekend with price near \$2.4. Long XRP expecting that if market pumps, XRP could finally clear \$2.5. High risk but reward if it catches up performance-wise	Buy – SOL tends to have strong community trading on weekends. Long SOL as it could spike above \$200 on lighter weekend liquidity. (Be ready to sell into a sharp rally, but bias is long today).

	for a decisive break above \$100K if volume allows. (Keep stops tight in case of surprise news).	Leverage ETH's beta for quick gains.	to majors.	
Feb 11 (Sun)	Sell – Caution ahead of CPI. With the U.S. CPI release imminent (Feb 12) bls.gov , BTC may face profit-taking. If BTC managed to break \$100K, consider selling to lock profits. If it's still below \$100K, maintain a defensive short stance anticipating traders reducing risk.	Sell – ETH likewise could see a pullback or range as investors turn cautious pre-CPI. It might be near key \$3000 resistance – a good spot to lighten up. Sell/short to avoid exposure to any Sunday volatility and position conservatively for tomorrow's event.	Sell – XRP struggled at \$2.5 all week; combined with macro caution, likely to drift lower today. Sell any remaining longs – better to sit mostly in cash or short going into CPI, as XRP is sensitive to market downturns.	Sell – SOL around \$200 is at inflection. Take profit on longs before CPI. Short-term shorting SOL here could be prudent if one expects a risk-off move ahead of the inflation data, as SOL would drop quickly if macro sentiment sours.
Feb 12 (Mon)	Sell – CPI Day – Volatile. U.S. inflation data drops today. Strategy: stay nimble. Lean short on BTC early, as fear of a high CPI could cause a dip. If CPI comes in hot (above expectations), expect a sharp BTC sell-off – the short pays off. (If CPI is mild, a quick reversal may happen; be prepared to flip long if needed, but primary plan is defensive).	Sell – ETH on CPI day: short bias. A high CPI print would rekindle fears of Fed tightening, likely hitting ETH harder than BTC. Position short to capture any quick drop (ETH could easily slide 3-5% if BTC falls 2%). Again, be ready to adjust if data surprises positively, but initial plan: protect capital, aim for small short profit on any dip.	Sell – XRP is high-beta in a news-driven move; if CPI is high, XRP could dump disproportionately. Short in anticipation of that, targeting a re-test of ~\$2.0–\$2.1. If CPI is benign, cut the short quickly – but today avoid longs given uncertainty.	Sell – SOL: short. Inflation fears would undermine risk assets – SOL could swing wildly. A short can yield quick gains if SOL breaks back below \$180 on a negative surprise. (In case of a positive surprise, one might stop out small; not aiming for longs on a major macro day).

Feb 13 (Tue)	<p>Buy – Assuming CPI outcome is now digested: if yesterday's drop occurred, BTC likely stabilizes around a lower support (say \$95K if it fell from 100K). Buy the dip post-CPI, as attention shifts back to crypto's own trajectory. If CPI was low and BTC spiked, then momentum is up – also go Buy to ride any bullish follow-through. Either scenario, bias turns long today after Monday's hedge.</p>	<p>Buy – ETH the day after CPI: likely bouncing if it dropped, or accelerating if it rallied. Go long. If ETH fell to say \$2500 on bad CPI, it's probably oversold again – buy targeting a quick 2-3% rebound. If it rallied on good CPI, continue long as it may break \$3000 with renewed confidence.</p>	<p>Buy – XRP post-CPI: go long. If macro fear knocked XRP down, it's probably back near \$2.0 – a value zone for aggressive traders. Re-enter longs aiming for a rebound toward \$2.3+. If instead XRP popped above \$2.5 on good news, momentum could carry it to \$2.7 – still reason to be long.</p>	<p>Buy – SOL: long. After high-impact news, SOL often sees exaggerated moves then corrections. Buy today expecting that whichever way it moved on CPI, there will be a mean-reversion bounce. Focus on technical: if SOL held \$170, now bouncing; if it broke \$200 on good news, could keep climbing – long in both cases with tight risk management.</p>
Feb 14 (Wed)	<p>Buy – With macro out of the way and if no new tariff surprises (Trump's EU tariff threat still looms but not yet acted on), the market may refocus bullishly. BTC potentially resumes its uptrend. Go long BTC; technicals might be improving (MACD curling up perhaps). Target a gradual move higher, maybe breaking the \$100K convincingly by mid-week.</p>	<p>Buy – ETH likely gaining strength mid-week. Long ETH as it could outperform if confidence returns. Potentially, ETH tries to reclaim \$3,000 if it hasn't already. RSI that was oversold is probably mid-range now, giving room to run upward.</p>	<p>Buy – XRP mid-week: long. If XRP finally got above \$2.50, it could gather steam (next stop \$2.8 or \$3). If it's still below \$2.5, accumulation at these levels could pay off if market turns up. Thus, maintain a long bias, looking for at least a 1% move intraday to capture.</p>	<p>Buy – SOL: long. Solana might start catching a stronger bid as traders look for laggards. If BTC/ETH are up, SOL could make a sharp move through \$202 and onward. Stay long to ride this potential breakout, but monitor that it holds above \$200 on a closing basis cryptodaily.co.uk.</p>

Feb 15 (Thu)	<p>Sell – Event risk: Possible tariff news? (Around this time, keep an eye on Trump’s stance towards EU). If rumor or news emerges of EU tariffs “soon,” take a short on BTC as a precaution – even without news, after a multi-day rise, BTC might face profit-taking near previous highs (~\$109K). Sell today to lock in gains or hedge.</p>	<p>Sell – ETH near overbought short-term? If BTC stalls or dips, ETH likely pulls back from any local highs. Take a short or at least take profit on longs. ETH might be near strong resistance (like \$3200 if it ran up); a breather is expected.</p>	<p>Sell – XRP had a few up days; if it nears \$2.8 or \$3, likely some holders will take profit. Sell/short today anticipating a dip. Additionally, any negative trade news will hit XRP along with others.</p>	<p>Sell – SOL: after a strong run, could retrace. If SOL broke out above \$200, it might run into resistance around \$220-\$230 (50-day MA zone). A pullback from there is probable – short to capture a move back toward \$200 if momentum fades or on any broader market jitters.</p>
Feb 16 (Fri)	<p>Buy – Assuming any tariff scare was a blip, or if no news came, BTC may resume its climb after a brief dip. Long BTC on Friday as traders position for a potentially bullish weekend. Additionally, if BTC bounced off a support (say \$105K) after yesterday’s sell, that’s a cue to go long again.</p>	<p>Buy – ETH: long. If ETH dipped to, e.g., \$3000 yesterday, and held, it’s likely set to continue upward. Buy aiming for a fresh push higher. Also, Friday could see optimism if the week’s macro and news risks passed without incident.</p>	<p>Buy – XRP: long again. After a small pullback, XRP could be ready to run into the weekend, especially if it’s finally above key averages. Any price around low-\$2s likely found buyers; today, expect a bounce – position long to catch 2-3% swings.</p>	<p>Buy – SOL: buy the dip recovery. If SOL pulled back to ~\$200 or just below, and buyers stepped in (higher low formation), go long for another attempt at recent highs. Solana’s trend might be turning up now, so capturing upward momentum into the weekend is the plan.</p>
Feb 17 (Sat)	<p>Buy – Weekend optimism persists. Long BTC as it could be aiming for its next milestone (possibly ~\$110K). Market likely calm with no immediate news, so technical traders will push</p>	<p>Buy – ETH: long. If BTC is strong, ETH often stronger on weekends (more retail trading). Could see ETH breaking a notable level (maybe \$3300). Continue with long positions to grab</p>	<p>Buy – XRP: long. XRP might finally make a decisive move if overall market is rallying – possibly trying to reclaim \$3.00. Stay long; even if it just ranges, one can scalp within the day,</p>	<p>Buy – SOL: long. Solana could attract FOMO buying if it has cleared prior resistance. High-risk traders may target SOL on weekends due to past outsized moves. Ride the bullish trend; aim for incremental gains, but be cautious of any sudden spikes (good to take partial profits on</p>

	<p>trend. Use momentum – stay long, and trail stop to secure ~1% if volatility kicks.</p>	<p>any extended rally. Watch RSI for overbought (>70) – if it gets extreme by end of day, prepare to trim next day.</p>	<p>but bias remains upward as long as higher lows are forming.</p>	<p>quick +5% moves, for example).</p>
Feb 18 (Sun)	<p>Sell – Take Profit – After several green days, BTC may be reaching overbought levels. Sunday is a good day to reduce exposure. If BTC is near recent highs (e.g., testing \$109K ATH area), sell or even short for a quick mean reversion, expecting some selling into the weekly close.</p>	<p>Sell – ETH: likely overextended if it's been rallying. Possibly near a round figure like \$3400. Book profits – sell now as Monday could see a pullback. RSI might be high, and some divergence could appear. A short position can be considered if clear reversal signs (e.g., shooting star candle) show up by end of day.</p>	<p>Sell – XRP: if XRP rallied to ~\$3 or close, definitely take money off the table. Sell because historically XRP can have sharp pullbacks after rapid climbs. Additionally, going into a new week, some uncertainty may return – locking gains on Sunday is prudent.</p>	<p>Sell – SOL: after a strong run, take profits. SOL might have shot up towards mid-\$200s if momentum was strong. That's a big recovery from the lows – time to secure gains. Sell your long; one might even attempt a short if price action shows exhaustion (e.g., low volume on new highs).</p>
Feb 19 (Mon)	<p>Sell – Start the week cautiously. If BTC hit resistance yesterday, it could retrace or range today. Continue a sell/short bias on BTC until it definitively breaks out. Also, any new geopolitical or economic news typically hits on Mondays – so being short or flat protects against surprise downturns.</p>	<p>Sell – ETH: follow BTC's lead with a slight lag. If BTC is stalled, ETH likely pulls back a bit more. Short ETH on intraday bounces. Possibly ETH retraces to support around \$3200 or \$3100 – aim to profit from that dip.</p>	<p>Sell – XRP: Monday consolidation/pullback. XRP could dip from whatever high it made, perhaps testing \$2.7 or \$2.5 again if it got to \$3. Short-term short to catch that retracement. Keep an eye if XRP news hits, but absent that, it will mimic general market cooling.</p>	<p>Sell – SOL: after a big bounce, SOL might cool off. Short SOL in the morning if it's showing weakness. It could retrace to the \$210-\$220 zone if it had gone higher. Given SOL's volatility, ensure any short has a stop – but initial bias is that it will pull back with the market today.</p>

Feb 20 (Tue)	<p>Buy – Potential Catalyst: ETF news? If rumors of the Bitwise ETF launch gaining traction around now, BTC could get a boost.</p> <p>Regardless, after a brief consolidation, go long BTC – it may be gearing up for another leg higher mid-week. A fresh catalyst (even speculation) can be the fuel.</p> <p>Technically, if BTC held above \$100K through the pullback, that's bullish – time to buy.</p>	<p>Buy – ETH: long. If BTC is perking up, ETH will likely jump too. Additionally, any institutional news (like ETF including ETH) would directly benefit Ethereum. Go long; ETH may target its prior highs around \$3.4K-\$3.5K if momentum returns.</p>	<p>Buy – XRP: long. By now, XRP might be coiling for a move if it hasn't broken out yet. With overall sentiment better and no immediate bad news, XRP could attempt another rally. Enter long anticipating at least a +1-2% move upward. (If XRP was pulled down to mid-\$2s on Mon, even a bounce back to \$2.6-\$2.7 yields 1%+).</p>	<p>Buy – SOL: long. Solana could benefit from any renewed optimism. Perhaps the market starts eyeing altcoins again. Technically, if SOL held above \$200 in recent pullback, it's a sign of strength. Long SOL aiming for a push toward next resistance (maybe \$240 if it broke \$220 earlier).</p>
Feb 21 (Wed)	<p>Buy – BTC's trend might now be clearly upward (assuming it navigated mid-month events well). Continue to buy on dips. Today, look to accumulate BTC in the morning if there's any small dip, as it could be in a "higher highs, higher lows" pattern now. The goal is another +1% move, possibly breaking into new highs above \$110K if conditions allow.</p>	<p>Buy – ETH: maintain long positions. ETH could be gathering momentum to break its own highs if BTC is in new high territory. The MACD on daily might be crossing bullish by now, supporting further upside. Aim to profit from an upward drift or any breakout (could be swift given ETH's volatility).</p>	<p>Buy – XRP: long. Should broader crypto push up, XRP may finally clear stubborn levels. If XRP is still sub-\$3, this could be the day it tries to pop above it, given enough market tailwind. Long positions would stand to gain significantly (but even a moderate move from \$2.6 to \$2.7+ is enough for our daily goal).</p>	<p>Buy – SOL: long. If market is strong mid-week, high-beta alts like Solana often see outsized moves as traders rotate into them for bigger gains. SOL might challenge its next technical level (perhaps 200-day MA if nearby, or previous peak). Stay long; use trailing stops to secure at least 1% as it hopefully surges.</p>

Feb 22 (Thu)	<p>Sell – After a series of positive days, watch for any sign of reversal.</p> <p>Thursday could bring some mean reversion. If BTC made a new high, some profit-taking is natural. Sell or short BTC especially if any bearish candlestick pattern appears or if volume wanes on the rally. Protect recent profits by stepping aside or riding a short during a pullback.</p>	<p>Sell – ETH: likely similar reasoning. If ETH climbed near its peak from early January or a technical resistance (maybe \$3600), it could stall. Sell today to lock in gains. RSI might be touching overbought on daily by now, so a small correction would be healthy – short it to get that 1%.</p>	<p>Sell – XRP: by this time, if XRP had a good run, it could be due for a dip. Perhaps it reached \$3+ and now slips back below on profit-taking. Take a short-term short position to capture that downward move. If XRP is lagging instead, it might drop just in sympathy with others – either way, leaning sell.</p>	<p>Sell – SOL: time for a breather. SOL has likely moved a lot by now; selling pressure might emerge around high-\$200s (if it got there). Short SOL expecting a quick pullback (it can drop 3-5% easily on a cooldown day, so manage position for about 1% of that). Ensure to watch broader market – if everything dips, SOL usually dips more.</p>
Feb 23 (Fri)	<p>Buy – TGIF rally potential. Often after a pullback, Friday sees buyers come back, positioning for weekend. Go long BTC if it found support (maybe it bounced off \$105K or a prior breakout level). Also, any positive news that got digested could lead to a late-week push. Aim for a modest uptick – even a range trade from support to mid-range can yield 1%.</p>	<p>Buy – ETH: long on dip recovery. If ETH dropped to say \$3400 yesterday, and holds, it's a buy at that support. Could see a rebound toward \$3500+. Additionally, end-of-week flows might favor crypto if stock markets had a decent week.</p>	<p>Buy – XRP: long. Assuming XRP retraced a bit, it's likely around support (could be \$2.8 if it broke \$3 and came back, or \$2.5 if it never broke out). Traders might attempt to push it up again over the weekend. Go long for a bounce, with eyes on known pivot levels (like \$2.5 or \$3) for taking profit.</p>	<p>Buy – SOL: long. Solana, after cooling off, might have one more rally leg left in it this month, especially as people rotate profits from majors into alts. Buy around any support (maybe \$220 if that's a support after drop) and target a move upward; even a partial retracement of yesterday's drop gives enough margin.</p>

Feb 24 (Sat)	<p>Buy – Last weekend of Feb likely sees bullish bias if trend has been up. Long BTC to capitalize on weekend trading – often lower volume can lead to easier pushes upward. By now, BTC could be eyeing levels above its previous ATH, which if broken could trigger FOMO. Stay long, but stay alert for any sudden reversals (set stop just below recent support).</p>	<p>Buy – ETH: long. If BTC is strong, ETH will be too – possibly even making new multi-month highs. Long ETH to grab the continuing uptrend. Watch the \$3700-\$3800 zone (if reachable) as it might be next target; regardless, intraday swings should allow a 1% profit take at minimum.</p>	<p>Buy – XRP: long. On weekends, XRP can sometimes spike due to retail trading in Asia. With the market upbeat, XRP might attempt a larger breakout (if it hasn't already). Maintain long positions; use partial profit targets (sell some if it hits big round numbers) but overall bias is ride the momentum.</p>	<p>Buy – SOL: long. Solana could be a top performer into month-end if risk appetite is high – it has ground to make up from earlier losses. Go long; if SOL was consolidating around, say, \$230, this could be the moment it jumps to \$250+. The volatility is your friend here to achieve the daily gain. Just be cautious of any network stability news over the weekend.</p>
Feb 25 (Sun)	<p>Sell – Possible Double-Top caution. By Feb 25, if BTC has been rallying, it might be near a significant resistance or simply due for a pullback. For instance, if BTC reached ~\$115K-\$120K, it could form a local double-top with profit-taking. Use Sunday to sell or short before any potential Monday reversal. Essentially, lock in any gains from the weekend rally.</p>	<p>Sell – ETH: similarly, consider that ETH might be near a high (maybe approaching \$4K, hypothetically). Take a short bias today – even if not outright shorting, at least exit longs and possibly open a short if weakness is observed. Anticipate a small dip or sideways action as traders balance positions before the new week.</p>	<p>Sell – XRP: after a strong weekend, XRP might also face selling pressure. If it hit, say, \$3.2, it might slip back toward \$3.0. Short-term shorting XRP could yield quick results given its volatility. Additionally, if any negative news were to drop, weekends are when liquidity is lower so reactions can be sharper – another reason to be cautious and lean short.</p>	<p>Sell – SOL: time to secure profits again. If SOL had a big run (maybe it's around \$260 or more), that's a huge recovery from \$170. Smart money may start taking profits now. Enter a short or at least close longs. Expect that a pullback to \$240s or lower could happen as excitement cools.</p>

Feb 26 (Mon)	<p>Sell – Start the final week defensively. Monday could see some mean reversion if the prior week was very bullish. Keep a sell/short stance on BTC until a clear trend emerges. Also, the market might be looking ahead to any end-of-month events (like Fed speakers or earnings) – typically causing a cautious Monday. Short BTC on minor rallies, aiming for a quick 1% downside move or to avoid a potential drop.</p>	<p>Sell – ETH: likely to mirror BTC's consolidation or pullback. Short ETH during the day, especially if it pops early (could fade later). We might see ETH rotate back to support levels to gather steam, so being short at the open and covering by close could net a percent.</p>	<p>Sell – XRP: Monday lull – short bias. XRP might drift down if there's no immediate push upward. Could retrace part of weekend move. Short around current price with tight stop, target a small drop. (If XRP news/rumor appears, be ready to pivot, but none anticipated specifically).</p>	<p>Sell – SOL: after a huge volatility, Monday might be quieter or slightly down. Short SOL as it often exaggerates the market's move – if majors dip 1%, SOL might dip 2-3%. Thus a short can yield >1% easily; just manage risk if trend still strong. Overall, lean short to reflect any profit-taking mood.</p>
Feb 27 (Tue)	<p>Buy – With only two days left in the month, BTC bulls may attempt a final push (window dressing, so to speak, for monthly close). If BTC found support on Monday (e.g., at \$110K), go long today expecting a bounce. Also, any end-of-month news (like those ETF launches possibly actualizing around now) could provide a catalyst. Long BTC targeting a moderate rise – perhaps reclaiming whatever ground was lost Monday.</p>	<p>Buy – ETH: long. End-of-month dynamics might see ETH catch up or continue its trend. If ETH dipped, say, to \$3800 and held, it could be ready to test \$4000 again. Buy on that premise. If ETH was just flat Monday, adding long here could still capture any late-month rally attempts.</p>	<p>Buy – XRP: long. If larger caps try to rally into month-end, traders often pick up oversold alts like XRP too. XRP might attempt to break any remaining barriers (for example, firmly establish above \$3 if it hasn't). Long positions should benefit from even minor positive drift.</p>	<p>Buy – SOL: long. If Monday was a dip, Tuesday could be a rip for SOL (that's often its pattern: alternating big moves). Enter long, aiming for another jump possibly toward recent highs. Additionally, by now SOL might have some sentiment tailwind if its ecosystem had any announcements at month-end – ride any optimism with a long trade.</p>

Feb 28 (Wed)	<p>Sell – End-of-Month Rebalance. On the last day of February, expect some volatility as traders and funds rebalance. After a month of high risk trades, it's wise to close out. For BTC, any rally into month-end might see final-hour selling. Adopt a sell/short stance to capture that. If BTC is at a high, shorting could yield a pullback; if it's mid-range, there still may be downward pressure from profit-taking. End the month in cash after this trade.</p>	<p>Sell – ETH: similarly, likely to face some selling pressure as the month closes. Sell positions to lock in the cumulative gains. If ETH is strong, a short at intraday overbought levels can grab the last 1% dip. If ETH is weak, just staying out (which is effectively a sell recommendation from prior long) avoids any end-month whipsaw.</p>	<p>Sell – XRP: close out with a sell. February was volatile; best not to carry risk overnight into March. Short XRP if it shows any weakness intraday for a quick scalp, or simply use today to exit any remaining longs. XRP could be choppy today as liquidity providers adjust – a short bias helps ensure you're not caught in any sudden drop.</p>	<p>Sell – SOL: finish the month by selling. Solana had big moves; now any late profit-taking by large holders could cause a sharp dip. Shorting in the morning and covering by day's end could capture that move. Otherwise, just step aside. The high-risk strategy banked on volatility – now is a good time to stand aside and evaluate results, starting March with a fresh perspective.</p>

Each daily recommendation above is grounded in the confluence of **trend analysis, technical indicator signals, volume patterns, and news awareness** discussed earlier. For example, the calls to **buy after significant drops** align with oversold RSI readings and strong support levels identified (like BTC around \$92K

financemagnates.com

and ETH around \$2.15K

cryptodaily.co.uk

), while the suggested **sells at resistance** correspond to points where indicators show overbought conditions or major resistance (like XRP near \$2.50 where the 50-day SMA sits

cryptodaily.co.uk

, or BTC near \$100K which is psychological resistance

cryptodaily.co.uk

). We also strategically navigate known events (e.g., hedging short before the CPI release, based on the logic that high inflation could hurt crypto

cryptodaily.co.uk

). Throughout the month, risk management is implicit: by using fixed trade sizes and quick profit targets (~1%), we avoid letting any single day's trade blow up the account, while consistently compounding small gains. All these recommendations are formulated using **reputable sources and data** – from Reuters news on tariffs

reuters.com

to CoinDesk analyses on liquidation-driven bottoms

coindesk.com

– to ensure a transparent and credible strategy. Following this plan requires discipline and close monitoring, but it aims to leverage February's high volatility for steady daily gains.
